Solar still efficiency (η) is the amount of energy utilized in vaporizing water in the still over the amount of incident solar energy on the still (Q_t in J/m² day). These can be expressed as: Solar still production: $M_e = Q_e / L$ Solar still efficiency: $\eta = Q_e / Q_t$. Typical efficiencies for single basin solar stills approach 60 percent.

Solar Still Basics

A solar still distills water with substances dissolved in it by using the heat of the Sun to evaporate water so that it may be cooled and

collected, thereby purifying it. They are used in areas where drinking water is unavailable, so that clean water is obtained from dirty water or from plants by exposing them to sunlight.

Johannes Kepler (1571-1630 CE) was fortunate enough to inherit an extensive set of naked-eye solar, lunar, and planetary angular position data from the Danish astronomer Tycho Brahe (1546-1601 CE). This data extended over many decades, and was of unprecedented accuracy. Although Kepler adopted the heliocentric approach of Copernicus,
